The State of The Art of Computer Programming

Donald E. Knuth Computer Science Department Stanford University Stanford, California 94305

This report lists all corrections and changes to volumes 1 and 3 of the Art of Computer Programming, as of May 14, 1976. The changes apply to the most recent printings of both volumes (February and March, 1975); if you have an earlier printing there have been many other changes not indicated here. Volume 2 has been completely rewritten and its second edition will be published early in 1977. For a summary of the changes made to volume 2, see SIGSAM Bulletin 9, 4 (November 1975), p. 10f -- the changes are too numerous to list except in the forthcoming book itself.

On any given day the author likes to feel that the last bug has finally disappeared, yet it appears likely that further amendments will be made as time goes by. Therefore a family of computer programs has been written to maintain a collection of errata, in the form printed here, but encoded as an ad-hoc sequence of ASCII characters. The author wishes to thank Juan Ludlow-Saldivar for the enormous amount of help he provided in order to get this system rolling. (Some readers who have access to the Stanford A.I.-Lab computer may wish to consult the change file before they report a "new" error; the file name is ACP.MAS [ART, DEK]. Entries for page nnn of volume k begin with ßkOlnnn (but change the Ol to DD if nnn is the Arabic equivalent of a Roman numeral); since "B" is the control character "¡C", you may rather search for simply the string "kOlnnn". The text of the correction usually includes special coder following the symbol " | ", for things like font changes, etc.)

The author thanks all the bounty hunters who have reported difficulties they spotted. The reward to first finder of each error is still ${\it ll}$ for the first edition and ${\it ll}$ for the second, gratefully paid. Volume ${\it ll}$ remains rather far from completion, so there is plenty of time to work all the exercises in volumes ${\it ll}$ - ${\it ll}$ and to catch all the remaining errors therein.

This research was supported in part by Mational Science Foundation grant MCS 72-03752 AO3 and by the Office of Maval Research contract NOCO14-76-C-0330. Reproduction in whole or in part is permitted for any purpose of the United States Government.

1.475 exercise 41 line 4 98 1/4 ~ 1/8 (twice) 2,465 99 exercise 31 We have M [This sum was first obtained in closed form by J. F. Pfaff, Nova acta acad. scient. Petr. 11 (1797), 38-57.] We have 1,460 100 and extending to page 487 change B to B (Roman type) in the solutions to exercises 40, 41 (twice), 42, 48 (twice). 7.466 exercise 14 101 n+4 ~ n+1 1,454 exercise 10 line 2 102 (25) 🔷 (17) 2.454 exercise 15 103 1.ne 1: $zG_{n-2}(z)$, $\sim zG_{n-2}(z) \cdot \delta_{n0}$, line 3 (the displayed formula): delete the period, then add a new line: when $z \neq -1/4$; $G_n(-1/4) = (n+1)/2^n$ for $n \ge 0$. bottom of page, a new answer to exercise 1.2.11.2-3: 104

3. ${}^4R_{2k}$! $\leq {}_4B_{2k}!/(2k)!$! $f_1^{-n} \cdot !f^{(2k)}(x)!dx$. [C. H. Reinsch observes that $R_{2k} = f_1^{-n}(B_{2k+2} - B_{2k+2}(\{x\})) \cdot f^{(2k+2)}(x)dx/(2k+2)!$, and that $B_{2k+2} - B_{2k+2}(\{x\})$ always has between 0 and (2-2-2k-1) B_{2k+2} . Therefore if $f^{(2k+1)}(x)$ but not $f^{(2k+3)}(x)$ tends monotonically to zero, (13)

still holds for some ℓ with $0 < \ell < 2 - 2^{-2k-1}$.]

225

Constructing lower bounds. Theorem M shows that the "information theoretic" lower bound (2) can be arbitrarily far from the true lower bound; thus the technique used to prove Theorem M gives us another way to discover lower bounds. Such a proof technique is often viewed as the creation of an adversary, a permicious being who tries to make algorithms run slowly. When an algorithm for merging decides to compare $A_i:B_j$, the adversary determines the fate of the comparison so as to force the algorithm down the more difficult path. If we can invent a suitable adversary, as in the proof of Theorem M, we can ensure that every valid merging algorithm will have to make a rather large number of comparisons. (Some people have used the words 'oracle' or 'demon' instead of 'adversary'; but it is preferable to avoid such terms in this context, since 'oracles' have quite a different connotation in the theory of recursive functions, and 'demons' appear in still a different purse within languages for artificial intelligence.)

We shall make use of constrained adversaries, whose power is limited with regard to the outcomes of certain comparisons. A merging method which is under the influence of a constrained adversary does not know about the constraints, so it must make the necessary comparisons even though their outcomes have been predestined. For example, in our proof of Theorem M we constrained all outcomes by condition (5), yet the merging algorithm was unable to make use of this fact in order to avoid any of the comparisons.

The constraints that we shall use in the following discussion apply to the left and right ends of the files. Left constraints are symbolized by

memory. It \longrightarrow memory. The difference between $\lg \lg N$ and $\lg N$ is not substantial unless N is quite large, and typical files aren't sufficiently random either. Interpolation

3,417 new paragraph after line 14:

266

Interpolation search is asymptotically superior to binary search; one step of binary search essentially replaces the amount of search, n_i by $\frac{1}{2}n_i$, while one step of interpolation search essentially replaces n by \sqrt{n} if the keys in the table are randomly distributed. Hence it can be shown that interpolation search takes about $\lg \lg N$ steps on the average. (See exercise 22.)

that the resulting maximum subtree weight, $\max(w(0,k-1),w(k,n))$, is as small as possible. This approach can also be fairly poor, because it may choose a node with very small $p_{m{k}}$ to he the root; however, Paul J. Bayer has proved that the resulting tree will always have a weighted path length near the optimum (see exercise 36).

3,450 exercise 30

278

M16 ~ M41

3,450 new version of exercise 36

279

36. [M40] (Paul J. Bayer.) Generalizing the upper bound of Theorem G, prove that the cost of any optimum binary search tree with nonnegative weights must be at most the total weight $S = \Sigma_{1 \leq i \leq n} p_i + \Sigma_{0 \leq i \leq n} q_i$ times H + 2, where $H = \Sigma_{1 \leq i \leq n} (p_i/S) \lg(S/p_i) + \Sigma_{0 \leq i \leq n} (q_i/S) \lg(S/q_i)$;

$$H = \sum_{1 \le i \le n} (p_i/S) \lg(S/p_i) + \sum_{0 \le i \le n} (q_i/S) \lg(S/q_i);$$

in fact, the top-down procedure which repeatedly chooses roots that minimize the maximum subtree weights will yield a binary search tree satisfying this bound. Show further that the cost of the optimum binary tree search tree is 2S times $H = \lg(2H/e)$.

 $4.5N^2 + 2.5N - 6$. $4.5N^2 + 2.5N - 6$)u.

3.500 addendum to exercise 15

331

It is interesting to note that G(w,z) = F(-wz,z)/F(-w,z), where $F(z,q) = \sum_{n\geq 0} z^n q^{n^2}/\prod_{1\leq k\leq n} (1-q^k)$ is the generating function for partitions $p_1+\cdots+p_n$ into n parts, where $p_j \geq p_{j+1}+2$ for $1\leq j\leq n$ and $p_n\geq 0$ (cf. exercise 5.1-16).

to appear.] 🔷 333-339.]

원년년년 insert new paragraph before line -2:

345

G. Baudet and D. Stevenson have observed that exercises 3% and 38 combine to yield a simple sorting method with $(n \log n)/k + O(n)$ comparison cycles on k processors: First sort k subfiles of size $\le \Gamma n/k T$, then merge them in k passes using the "odd-even transposition merge" of order k. (To appear.)

362

 $B_k 2^{j(k-1)} \sim B_k / 2^{j(k-1)}$

ELEE exercise 34, new answer to part (b)

363

(b) In the $1/(e^{x}-1)$ part, it suffices to consider values of j with $x \in 2$ ln n. For $1 \le x \le 2$ ln n we have $\sum_{1 \le k \le n/x} (1-kx/n)^{n-1} + \sum_{k \ge 1} e^{-kx} + O(x^2e^{-x}/n)$. For $x \in 1$ we have $\sum_{0 \le k \le n} \binom{n}{k} B_k(x/n)^k + \sum_{k \ge 0} P_{k-1} k/k! + O(x^2/n)$.
